Can kidney damage be decreased or prevented when your child has a urinary tract infection?

• About 1 in 7 children with urinary tract infections will develop kidney damage (scarring).
• Scarring to the kidney is caused by the swelling and irritation that comes with an infection.
• The aim of the study is to find out if kidney scars can be decreased or prevented by using steroid medication with the use of antibiotics.

To enroll your child in this research study, your child must:
• Have a urinary tract infection today
• Be 2 months up to 6 years of age
• Not have another infection that requires antibiotics or any serious medical condition
• Donate a small sample of blood and urine
